#### **ABSTRACT**

A compiler is a computer program that transforms source code written in a programming language (the source language) into another computer language (the target language), with the latter often having a binary form known as object code. When executing, the compiler first parses all of the language statements syntactically one after the other and then, in one or more successive stages or passes, builds the output code, making sure that statements that refer to other statements are referred to correctly in the final code. Syntax analysis or parsing is the second phase of a compiler. A lexical analyzer can identify tokens with the help of regular expressions and pattern rules. But a lexical analyzer cannot check the syntax of a given sentence due to the limitations of the regular expressions. Regular expressions cannot check balancing tokens, such as parenthesis. Therefore, this phase uses context-free grammar (CFG), which is recognized by push-down automata. A syntax analyzer or parser takes the input from a lexical analyzer in the form of token streams. The parser analyzes the source code (token stream) against the production rules to detect any errors in the code. Parsing, syntax analysis or syntactic analysis is the process of analysing a string of symbols, either in natural language or in computer languages, conforming to the rules of a formal grammar. Syntactic analysis, or parsing, is needed to determine if the series of tokens given are appropriate in a language - that is, whether or not the sentence has the right shape/form. However, not all syntactically valid sentences are meaningful, further semantic analysis has to be applied for this. For syntactic analysis, context-free grammars and the associated parsing techniques are powerful enough to be used - this overall process is called parsing. There are many techniques for parsing algorithms, and the two main classes of algorithm are top-down and bottom-up parsing. The top-down parsing uses leftmost derivation, and the bottom-up parsing uses rightmost derivation.

## INTRODUCTION

# **Syntax Analysis**

In computer science, syntax analysis is the process of checking that the code is syntactically correct. The purpose of syntax analysis or parsing is to check that we have a valid sequence of tokens. Tokens are valid sequence of symbols, keywords, identifiers etc. The parser needs to be able to handle the infinite number of possible valid programs that may be presented to it. The usual way to define the language is to specify a grammar. A grammar is a set of rules (or productions) that specifies the syntax of the language (i.e. what is a valid sentence in the language). There can be more than one grammar for a given language. The parser analyzes the source code (token stream) against the production rules to detect any errors in the code. The output of this phase is a parse tree.

The syntax analyser for the C language by writing two scripts, one that acts as a lexical analyzer (lexer) and outputs a stream of tokens, and the other one that acts as a parser.

The lexer is known as the lex program. Lex reads an input stream specifying the lexical analyzer and outputs source code implementing the lexer in the C programming language.

# **Structure of Lex Program**

The structure of the lex program consists of three sections:

{definition section}

%%

{rules section}

%%

{C code section}

The definition section defines macros and imports header files written in C. It is also possible to write any C code here, which will be copied verbatim into the generated source file.

The rules section associates regular expression patterns with C statements. When the lexer sees text in the input matching a given pattern, it will execute the associated C code.

The C code section contains C statements and functions that are copied verbatim to generated source file. These statements presumably contain code called by the rules in the rules section.

# **Structure of Yacc Program**

The parser written is known as the Yacc program. The structure of the Yacc file is similar to that of the lexer, consisting of three sections:

```
{declarations}
%%
{rules}
%%
{routines}
```

The **declarations section** of a yacc file may consist of the following:

- %token identifies the token names that the yacc file accepts
- %start identifies a nonterminal name for the start symbol
- %right identifies tokens that are right-associative with other tokens
- %left identifies tokens that are left-associative with other tokens
- %nonassoc identifies tokens that are not associative with other tokens

The **rules section** consists of the context free grammar used to generate the parse tree. A general rule has the following structure:

```
nonterminal
```

```
: sentential form
| sentential form
......
| sentential form
:
```

Actions may be associated with rules and are executed when the associated sentential form is matched.

The **routines section** may include the C program that specifies the input file, action routines and other user defined functions

```

## **IMPLEMENTATION**

The Yacc program specifies productions for the following:

- Looping construct: while, for, do-while
- Data types: (signed/unsigned) int, float
- Arithmetic and Relational Operators
- Data structure: Arrays
- User defined functions
- Keywords of C language
- Single and Multi-line comments
- Identifiers and Constant errors
- Selection statement: (nested) if-else

The productions for most of them are straight-forward. A few important ones are:

```
compound_statement
    : '{' '}'
    | '{' statement list '}'
```

```
| '{' declaration list '}'
  | '{' declaration list statement list '}'
selection statement
  : IF '(' expression ')' statement %prec NO ELSE
  | IF '(' expression ')' statement ELSE statement
iteration statement
  : WHILE '(' expression ')' statement
  | DO statement WHILE '(' expression ')' ';'
  | FOR '(' expression statement expression statement ')' statement
  | FOR '(' expression statement expression statement expression ')' statement
jump statement
  : CONTINUE ';'
  | BREAK ';'
  | RETURN ';'
  | RETURN expression ';'
statement
  : compound statement
  | expression statement
  | selection statement
  | iteration statement
  | jump statement
```

After parsing, if there are errors then the line numbers of those errors are displayed along with a 'parsing failed' message on the terminal. Otherwise, a 'parsing complete' message is displayed on the console.

When a grammar is not carefully thought out, the parser generated from the grammar may face two kinds of dilemmas.

#### Shift-Reduce Conflict:

Enough terms have been read and a grammar rule can be recognized according to the accumulated terms. In this situation, the parser can make a reduction. If, however, there is also another grammar rule which calls for more terms to be accumulated and the look ahead token is just what the second grammar rule expected. In this situation, the parser may also make a shift operation. This dilemma faced by the parser is called the Shift/Reduce Conflict.

#### Reduce-Reduce Conflict:

Enough terms have been read and two grammar rules are recognized based on the accumulated terms. If the parser then decides to make a reduction, should it reduces the accumulated terms according to the first or second grammar rules? This type of difficulty faced by the parser is called the Reduce/Reduce Conflict.

#### **Handling Shift-Reduce and Reduce-Reduce Conflicts**

The yacc command is built with two internal rules for resolving these two ambiguities, sometimes called the disambiguating rules.

- 1. yacc resolves the Shift/Reduce Conflict in favor of shift operation. In plain English, this just means that it matches the longest input possible.
- 2. yacc resolves the Reduce/Reduce Conflict in favor of the first grammar rule.

In general, whenever it is possible to apply disambiguating rules to produce a correct parser, it is also possible to rewrite the grammar rules so that the same inputs are read but there are no conflicts. For this reason, it is important to write unambiguous grammar with no conflicts.

# **Solving Dangling Else Problem**

Whenever it is not possible to associate an 'else' to a closest 'if' in if-else statements, it gives rise to dangling else problem. In this case, the problem of dangling else occurs here, represented by #:

IF '(' expression ')' statement # ELSE statement

The question the parser must answer is "should I shift, or should I reduce". Usually, you want to bind the else to the closest if, which means you want to shift the else token now. Reducing now would mean that you want the else to wait to be bound to an older if.

We should specify the parser generator that "when there is a shift/reduce conflict between the token ELSE and the rule "selection\_statement -> IF ( expression )

statement", then the token must win". To do so, a name is given to the precedence of your rule (e.g., NO ELSE), and specify that NO ELSE has less precedence than ELSE.

```
//Precedences go increasing, So, NO_ELSE < ELSE %nonassoc NO_ELSE %nonassoc ELSE %nonassoc ELSE %% selection_statement : IF '(' expression ')' statement %prec NO_ELSE | IF '(' expression ')' statement ELSE statement ; %%
```

# **TEST CASES**

#### **Without Errors**

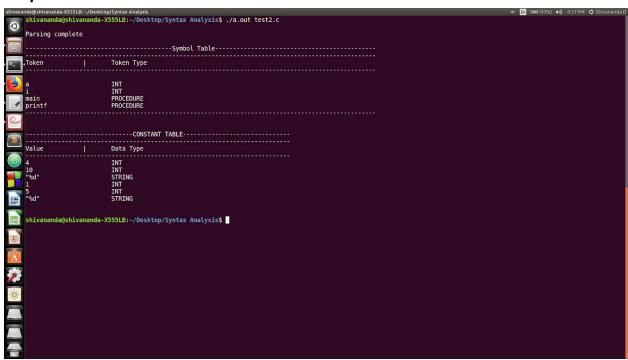

#### 1. test1.c

```
//without error - nested if-else
#include<stdio.h>
#define x 3
int main()
{
    int a=4;
    if(a<10)
    {
        a = a + 1;
    }
    else
    {
        a = a + 2;
    }
    return;
}</pre>
```

```

```

## 2. test2.c

```
//without error - while and for loop
#include<stdio.h>
#define x 3
int main()
{
  int a=4;
  int i;
  while(a<10)
```

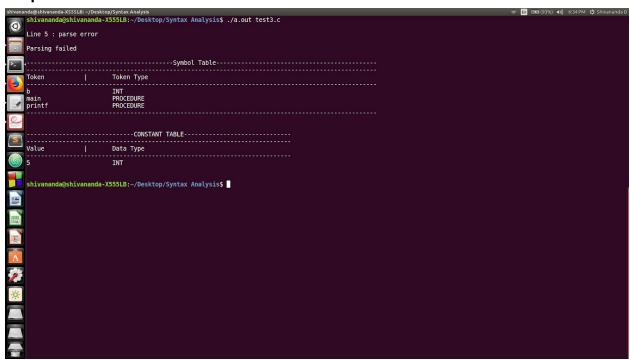

## With Errors

# 1. test3.c (missing multiple semicolon) #include<stdio.h> #define x 3

```
int main()
{
  int b=5
```

```
printf("%d",b);
  while(b<10)
  {
        printf("%d", b)
        b++;
  }
}</pre>
```

# 2. test4.c (misspelled keyword 'while' and unmatched parentheses)

```
#include<stdio.h>
#define x 3
int main()
{
   int a=4;
   whle(a<10)
   {
      printf("%d",a);
      j=1;</pre>
```

```

```

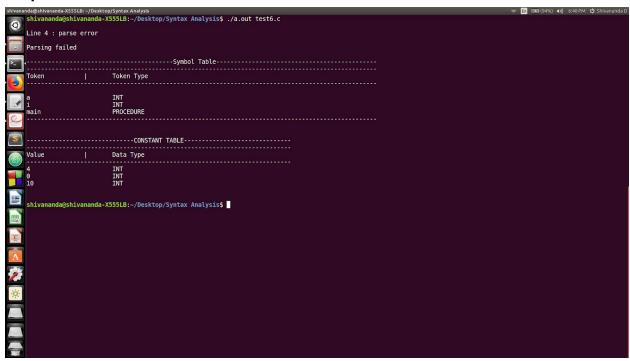

# 3. test5.c (dangling else problem)

```
#include<stdio.h>
#define x 3
int main()
{
   int a=4;
   if(a<10)
        printf("10");
   else
   {</pre>
```

```
As in the content of the content of
```

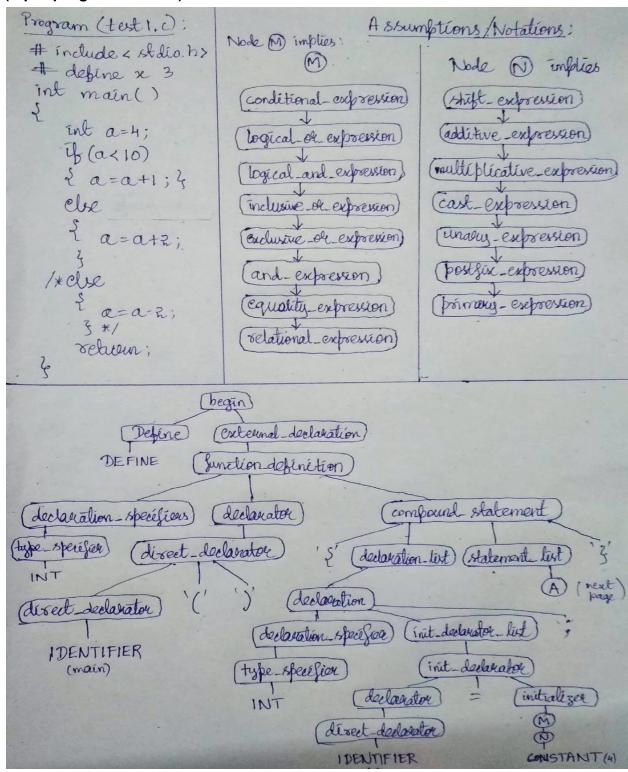

# 4. Test6.c (for loop syntax error)

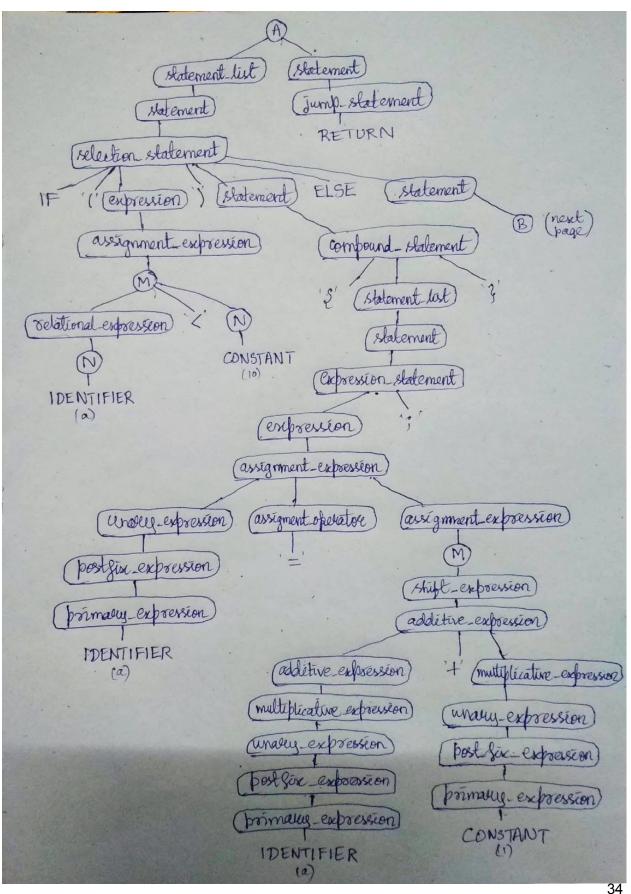

```
#include<stdio.h>
int main()
{
    int a=4, i;
    for(i=0;i<10)
    {
        printf("%d",i);
    }
}</pre>
```

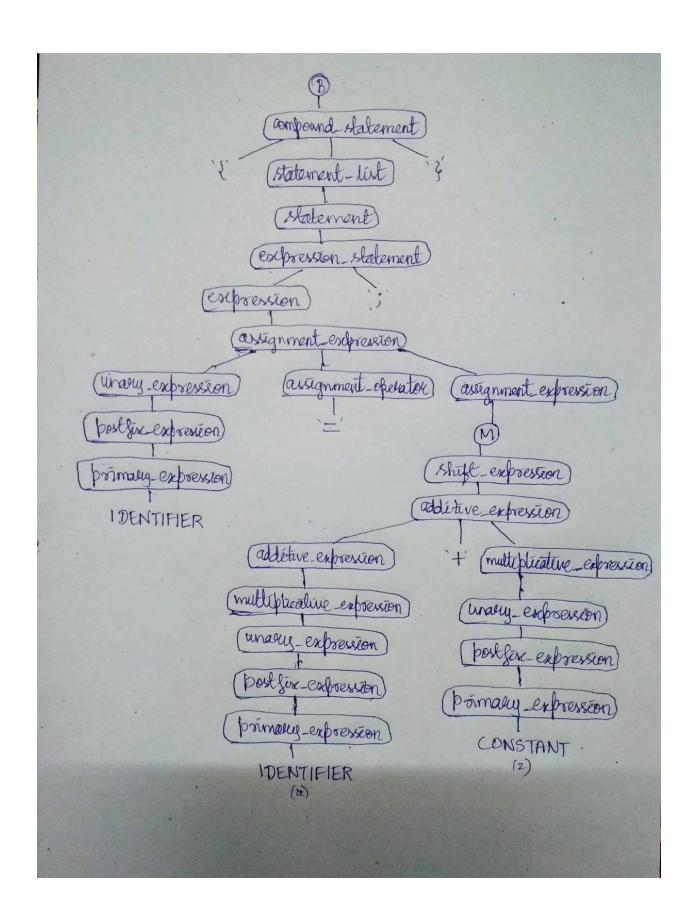

## **PARSE TREE**

(input program: test1.c)

## CONCLUSION

The lexical analyzer and the syntax analyzer for a subset of C language, which include selection statements, compound statements, iteration statements, jumping statements, user defined functions and primary expressions is generated. It is important to note that conflicts (shift-reduce and reduce-reduce) may occur in case of syntax analyzer if proper care is not taken while specifying the context-free grammar for the language. We should always specify unambiguous grammar for the parser to work properly.

#### **FUTURE WORK**

We have implemented the parser for only a subset of C language. The future work may include specifying the grammar for more pre-defined functions in C (like string functions, file read and write functions), goto jump statements and enumerations.
